**NOTE 1:** Appendix E should be filled out and submitted with each deliverable. Or, if the PICS: NE system permits, completely enter all applicable information in the PICS: NE Deliverable Form. The requirement is to ensure that all applicable information is entered either in the PICS: NE system or by using the NTRD Document Cover Sheet.

- In some cases there may be a milestone where an item is being fabricated, maintenance is being performed on a facility, or a document is being issued through a formal document control process where it specifically calls out a formal review of the document. In these cases, documentation (e.g., inspection report, maintenance request, work planning package documentation or the documented review of the issued document through the document control process) of the completion of the activity, along with the Document Cover Sheet, is sufficient to demonstrate achieving the milestone.

**NOTE 2:** If QRL 1, 2, or 3 is not assigned, then the QRL 4 box must be checked, and the work is understood to be performed using laboratory QA requirements. This includes any deliverable developed in conformance with the respective National Laboratory / Participant, DOE or NNSA-approved QA Program.

**NOTE 3:** If the lab has an NQA-1 program and the work to be conducted requires an NQA-1 program, then the QRL-1 box must be checked in the work Package and on the Appendix E cover sheet and the work must be performed in accordance with the Lab's NQA-1 program. The QRL-4 box should not be checked.

## **SUMMARY**

Uranium mononitride has been proposed for nuclear fuels, given its favorable uranium atom density and thermal conductivity. Current synthesis routes are either cost prohibitive or leave behind unwanted carbon or oxygen contaminants. Here, a route known as oxidative ammonolysis is explored to convert uranium tetrafluoride to uranium dinitride. Reaction products have been examined and phases determined. The study here shows the possibility to convert uranium fluoride phases to uranium nitride phases.

# ASSESSMENT OF FEEDSTOCK SYNTHESIS ROUTES FOR HIGH DENSITY FUELS

## 1. INTRODUCTION

There has been interest in the use of uranium nitrides as a nuclear fuel, in Gen IV reactors and as a way to improve neutron economics in current generation reactors. Uranium nitride (UN) possesses a higher uranium atom density than traditionally used uranium dioxide ( $\text{UO}_2$ ) fuel. The higher uranium atom allows for a greater neutronic penalty from accident tolerant fuel claddings. Uranium nitride also has a higher thermal conductivity than  $\text{UO}_2$ , resulting in lower centerline temperatures within the fuel.

Conventional uranium nitride synthesis routes include carbothermic reduction of the oxide or hydriding and nitriding the metal. Both routes have their drawbacks, carbon and oxygen impurities for the former, and the need for high purity uranium metal in the latter. A synthetic route starting from uranium fluorides is explored here. Starting with  $\text{UF}_4$  and heating under ammonia gas, a process known as oxidative ammonolysis,  $\text{UN}_2$  can be made, at lower processing temperatures and starting with standard U-F bearing species utilized in industry at the front end of fuel fabrication lines. This could also by pass the oxidation of  $\text{UF}_6$  and subsequent costly carbothermic reduction and nitridation steps that are currently proposed for UN fabrication at the commercial scale.  $\text{UN}_2$  can be readily decomposed to UN at elevated temperatures (1100 °C).

Here an experimental setup has been devised and four reactions have been performed. The reaction products have been analyzed for phases using XRD.

## 2. BACKGROUND

Current UN synthetic routes include hydriding and nitriding uranium metal and carbothermic reduction of the oxide. In the hydriding and nitriding route, high purity uranium metal is hydrided. The subsequent uranium hydride is then decomposed and nitrided in a purified nitrogen atmosphere. The resulting  $U_2N_3$  is then decomposed to UN at high temperature [1]. The downside to the hydride/dehydride/nitride method is the cost associated with high purity uranium metal and the proliferation concerns associated with uranium metal. In the carbothermic reduction route,  $UO_2$  is mixed with graphite powder and heated to reduce the oxide and form UC. The UC is then heated under a  $H_2$ - $N_2$  atmosphere to convert the UC to UN [2]. The drawbacks from the carbothermic reduction route include the vaporization of low vapor-pressure actinides and the inclusion of carbon impurities, as well as the high temperatures and long times involved.

A synthetic route using uranium fluorides and ammonia gas was published by Funk and Bohland, with  $UF_4$  reacting with  $NH_3$  at higher temperatures to form higher uranium nitrides [3]. The route was also used by Berthold and Hein and they proposed the intermediate phases of  $U(NH)F$  and  $U(NH_2)F_2$  [4]. Yoshihara et al explored the reaction of  $UF_4$  with Si and  $N_2$  to obtain the sesquinitride ( $U_2N_3$ ) [5]. More recently, Yeaman et al published an exploration of the oxidative ammonolysis of uranium fluorides [6]. The reaction of tetravalent ammonium uranium fluorides with an ammonia atmosphere at 800 °C was used to produce hexavalent  $UN_2$ , which was subsequently decomposed to UN. The reactions here were performed in quartz tubes, which are vulnerable to attack by the corrosive fluorine species produced in the reaction. This could lead to a source of oxygen and thus uranium oxide in the final product. The reaction was studied again showing the  $UN_2$  product to have less than 1.0 wt. %  $UO_2$  [7]. The route was further explored in Yeaman's [8] and Silva's [9] doctoral dissertations.

### 3. EXPERIMENTAL METHODS

#### 3.1 Fluoride Conversion Process

The starting material used in the oxidative ammonolysis process was uranium tetrafluoride ( $\text{UF}_4$ ), taken from LANL stock. The material had natural enrichment levels and was analyzed using XRD prior to the experimental investigations. The XRD is shown in Figure 1. The  $\text{UF}_4$  starting material contained a small amount, on the order of 1 weight %,  $\text{UO}_2$ .

Figure 1. XRD pattern of  $\text{UF}_4$  starting material, shown with lines from PDF database indicating  $\text{UF}_4$  (red) and  $\text{UO}_2$  (blue).

The experimental setup, shown in Figure 2, consisted of an Inconel 600 reaction vessel that could be sealed using valves on both ends. An Inconel sheathed Type K thermocouple was swaged into the reaction vessel to monitor the temperature of the reaction. The reaction vessel was placed in a clam shell furnace for heating in a chemical fume hood. The entire system up to the gas tank was evacuated to approximately 1 torr before every experiments. Ammonia gas was flowed during different segments of the experiment, as specified in Table 1, to determine optimal experimental parameters. The ammonia flow was set to maintain a pressure of approximately 500 torr (slightly sub-ambient). Approximately 1 gram of the  $\text{UF}_4$  starting material was loaded into an Inconel 600 boat and sealed in the reaction vessel in an Ar atmosphere glovebox ( $<1$  ppm  $\text{O}_2$ ). Following the experiment, the reaction vessel was evacuated and sealed before being transferred to the Ar glovebox where the vessel was opened and the material removed for XRD analysis.

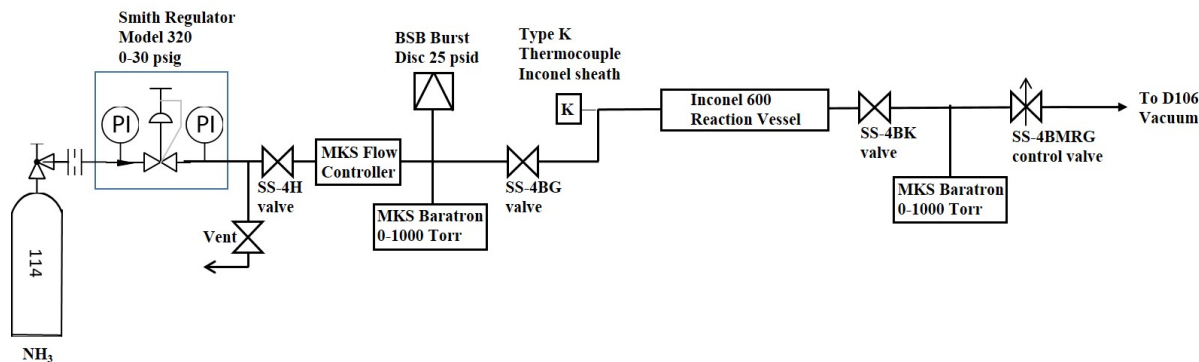

Figure 2. Manifold for the conversion of  $\text{UF}_4$  to  $\text{UN}_2$  using  $\text{NH}_3$  (g). This set up was in a chemical fume hood.

Four reaction conditions were explored to investigate the conditions that produce the highest quantity of  $\text{UN}_2$ . The reaction temperature was varied from 890 to 1050 °C, time at temperature was set for a duration of 1 to 4 hours, and the ammonia gas was flowed at different segments for the experimental procedure (i.e. heating, at temperature, cooling). The four reaction conditions are shown in Table 1.

Experiment Number	Temperature	Ammonia Flow	Time at Temperature
1	1050 °C	At Temperature	1 hour
2	1050 °C	At Temperature, Cooling	2 hours
3	890 °C	Heating, At Temperature, Cooling	2 hours
4	890 °C	Heating, At Temperature, Cooling	4 hours

Table 1. Experimental Conditions used for oxidative ammonolysis.

### 3.2 X-Ray Diffraction

X-ray diffraction (XRD) was used to analyze the samples after the oxidative ammonolysis experiments. A Bruker XRD (D2 Phaser, Bruker AXS, Madison, WI, USA) was used for analysis. The material resulting from each test condition was ground and homogenized using a mortar and pestle in an Ar glove box. The powder was encapsulated using a low background, airtight specimen holder ring (A100B138-B141, Bruker AXS, Madison, WI, USA). Each sample was scanned over a two theta range of 14 to 98°, using a 0.02° step size and a 2 second dwell time.

## 4. RESULTS AND DISCUSSION

The oxidative ammonolysis conversion of  $\text{UF}_4$  to  $\text{UN}_2$  is proposed to have the overall following reaction:

Not included in the balanced equation, are the possible intermediate species of  $\text{U}(\text{NH})\text{F}$  and  $\text{U}(\text{NH}_2)\text{F}_2$ . It is also possible that the reaction occurs between the  $\text{UF}_4$  decomposition products and the ammonia gas. The use of a residual gas analyzer may assist in shedding light on the reaction mechanism.

As discussed above, following the oxidative ammonolysis reaction, the reaction vessel was transferred to an Ar glovebox where the resulting powder was removed from the vessel and ground with a mortar and pestle for XRD analysis. The full pattern for all four runs and the starting  $\text{UF}_4$  is shown in Figure 3.

Figure 3. Diffraction patterns for the conversion of  $\text{UF}_4$  to  $\text{UN}_2$  for experiments 1-4 and the starting material  $\text{UF}_4$ .

The dominant phases seen in the diffraction patterns for the material following the conversion runs are  $\text{UF}_4$ ,  $\text{UF}_3$ ,  $\text{UO}_2$ , and  $\text{UN}_2$ . The  $\text{UO}_2$  is also present in the  $\text{UF}_4$  starting material. The  $\text{UF}_3$  is a decomposition product of  $\text{UF}_4$  that occurs at high temperatures. The  $\text{UN}_2$  is the final product of the oxidative ammonolysis reaction. There are also present some unidentified peaks, believed to belong to intermediate species, such as  $\text{U}(\text{NH})\text{F}$  and  $\text{U}(\text{NH}_2)\text{F}_2$  [4]. Shown in Figure 4 are the diffraction patterns from 20 ° to 40 ° with peaks for  $\text{UF}_3$ ,  $\text{UO}_2$ , and  $\text{UN}_2$  labeled for clarity of these phases. The unlabeled peaks belong to either  $\text{UF}_4$  (as can be compared to the starting material in the bottom most pattern) or an unidentified intermediate phase.

Figure 4. Enlarged region of the diffraction patterns with labeled peaks.

From the diffraction patterns, it is evident that Run 1 did not produce any  $\text{UN}_2$ , but did increase the level of  $\text{UO}_2$  present and formed some  $\text{UF}_3$  from  $\text{UF}_4$  decomposition. The lack of  $\text{UN}_2$  in the final product from Run 1 is most likely due to not being exposed to the ammonia atmosphere for a long enough period of time, especially upon cooling. Run 2 was the most successful conversion, with the prominent phase present as  $\text{UN}_2$ . The small  $\text{UF}_4$  peaks indicate the reaction consumed the majority of the starting material. The presence of  $\text{UF}_3$  and possible intermediate phases indicate that the reaction did not go all the way to completion, suggesting longer time may be needed. The diffraction pattern from Run 3 contains peaks belonging to  $\text{UF}_4$ ,  $\text{UO}_2$ , and  $\text{UN}_2$ , indicating an incomplete reaction. Run 4 has all phases present. The difference between Run 3 and Run 4 is a longer period at temperature. The increase in  $\text{UF}_3$  peaks and decrease in  $\text{UF}_4$  peaks indicate that a longer time at temperature leads to an increase in the decomposition of  $\text{UF}_4$ , regardless of the flowing ammonia gas. When looking at all four runs it is clear that flowing ammonia is necessary upon cooling the reaction vessel. This suggests that the primary reaction may take place between a decomposition product of  $\text{UF}_4$  and ammonia. The apparent completion of the reaction and lack of starting material leftover in Run 2 suggest that the higher temperature is more favorable, compared to Runs 3 and 4.

## 5. CONCLUSIONS AND FUTURE WORK

An experimental setup was constructed that would allow for the conversion of  $\text{UF}_4$  to  $\text{UN}_2$  while controlling the atmosphere and temperature. The reaction vessel and reaction boat were constructed out of Inconel 600 to limit corrosion and possible oxygen sources. Four reactions were performed varying the temperature, time at temperature, and flow of ammonia. The reaction material was then analyzed using XRD for the phases present. It is evident that the flow of ammonia is necessary at least at temperature and during cooling. It also appears that a higher temperature is more favorable for conversion to  $\text{UN}_2$ .

Future work includes repeating Run 2 and optimizing the reaction parameters to maximize the yield of the reaction. Work will also be done using a residual gas analyzer to determine what gases are evolved and during what part of the reaction. The next step in the process would be to take the high yield  $\text{UN}_2$  material and convert it to UN. To further minimize oxide impurities, the starting  $\text{UF}_4$  material could be cleaned of oxide impurities. This could possibly be done using ammonium bifluoride, which reacts with  $\text{UO}_2$  to form ammonium uranium fluorides.

While this reaction has not yet been optimized, this is a viable route to uranium nitride. The synthesis does not include the introduction of carbon into the system, and thus carbon impurities in the final product. This reaction is also performed at temperatures significantly lower than carbothermic reduction (1000 °C compared to 1800 °C). The reaction also uses  $\text{UF}_4$  as a starting material, which is found in the commercial processing of uranium and does not need accrue the expense and proliferation concerns of uranium metal.
